

Multi-Factor Authentication (MFA) Service

Current Usage

Currently used by WK for **more than 75 million** authentications per year.

Why use the SSC Multi-Factor Authentication (MFA) Service?

The MFA Service allows applications to add 2nd-factor authentication for business scenarios that already support 1st-factor authentication.

Relevant scenarios for new usages of MFA:

- WK identity management / authentication provider that doesn't already support MFA
- Application using its own proprietary login authentication that doesn't already support MFA
- Application using a WK-internal authentication provider that doesn't already support MFA
- Application using a 3rd-party authentication provider that doesn't already support MFA
- Application using a 3rd-party authentication provider that does support MFA, but it is too expensive
- Application requiring lightweight re-validation of identity during a critical user-initiated workflow

Supported modes of MFA authentication:

- SMS (API requires only a phone number)
- Voice (API requires only a phone number)
- Email (API requires only an email address)
- WK Authenticator mobile app
- Google Authenticator, Microsoft Authenticator, and other TOTP authenticator mobile apps
- Temporary access code (generated via support portal)
- “Remember My Device” cookies
- WhatsApp (coming in 2026)

Other important MFA features:

- lightweight MFA API can be called either via a REST API or through the MFA Client SDK (.NET and Java)
- standard UI to make default integration simple
- alternatively, optional custom UI can be implemented for application-specific requirements
- multiple providers for SMS, voice, and email (to provide high availability/deliverability)
- self-service admin portal
